## 1. Introduction

## 2. The Dataset

“The *Youth Risk Behavior Survey (YRBS)* measures health-related behaviors and experiences that can lead to death and disability among youth and adults.[...] Some of the health-related behaviors and experiences monitored are: - Student demographics: sex, sexual identity, race and ethnicity, and grade - Youth health behaviors and conditions: sexual, injury and violence, bullying, diet and physical activity, obesity, and mental health, including suicide - Substance use behaviors: electronic vapor product and tobacco product use, alcohol use, and other drug use - Student experiences: parental monitoring, school connectedness, unstable housing, and exposure to community violence [1]. It is a national survey conducted by CDC (Center for Disease Control and Prevention) and includes high school students from both private and public schools within the U.S. Data is collected from 1991 through 2021, we are only using the most recent data from 2021 though.

### 2.1 Preprocessing of the dataset

To preprocess the dataset, we first ran a summary on our dataset. The number of NAs seems to depend very much on the question. The variable “orig\_rec” only contained NAs and has therefore been removed, as well as the variable “site” which only contained “XX” entries. Variables q4 and q5 are already aggregated in “raceeth” and have also been deleted. The variable “record” seems to be an ID for the observations. This has to be considered later.

**2.2 Missing Data** There are around 19% NAs in the dataset. We will first exclude all the observations with NAs in the target related variables q25 to q29. Since we want to build our target variable on these questions, the target variable cannot be empty. For better results we do not want to impute the target variable. The amount of available data should be enough to just exclude these observations.

What if we just excluded every NA in the dataset? We will try and see if this is a viable option, since this would not just be quick and easy, but we would also just have “real” answers. The exclusion of NAs leads to a severe reduction in the number of observations. The original data consisted of 17138 observations while the reduced dataframe only has 4334 observations.

We need to assess the loss of information foremost in relation to our target variable. It seems like we still have a comparable ratio of observations for the categories in relation to the variables q25 to q29. Most changes are only minor.

**2.2.2 Omitting NAs vs Data Imputation** If we can really omit the NAs or if it may be necessary to impute the missing datapoints, depends on the type of missingness. If data is missing completely at random (MCAR), we can omit the NAs, if it is just missing at random (MAR) we would rather impute the data. To find out if we can just omit the data, an MCAR test was applied. It resulted in a p-value of 1, which means we cannot say for sure, that the data is not missing completely at random. We can assume that no imputation is necessary, but omitting the NAs is fine.

### 2.3 Reducing and balancing the dataset to 2000 observations

### 2.4 Naming and Factorizing the variables

First, the variables were named instead of encoded with the questions number.

Then, the categorical variables are factorized. For ordinary variables, the factors are ordered as well.

## **2.5 Simple Synopsis of the Dataset**

number of observations: number of variables:

datatypes: - nominal variables: - ordinal variables: (numeric variables:) - discrete variables: - continuous variables:

## **2.6 Target Variable**

As a target variable, we decided to calculate a score from 5 questions that reflects the suicide risk of the person (observation) in question. This score is aggregated with a rule based approach according to the accompanying Data User Guide.[2].

## **3. Additional Data Preparation**

### **3.1 Feature Reduction**

Since our dataset has lots of variables, we decided to start by excluding some variables depending on the estimated feature importance.

#### **3.1.1 Correlations**

#### **3.1.2 Feature Importance Algorithm**

### **3.2 Splitting the Data**

According to the project requirements we split our data in 60% Training, 20% Validation and 20% Testing Data.

## **4. Machine Learning Models**

### **4.1 Short Mathematical Overview on the used Methods**

#### **4.2 Fitting process**

#### **4.3 Hyperparameter Optimization**

Mithilfe eines Likelihood-Ratio Tests wird überprüft welches Modell das bessere ist.

Das optimierte Modell ist signifikant besser als das erarbeitete zum festgelegten Signifikanzniveau, die Nullhypothese des LR-Tests, dass das optimierte Modell nicht besser ist als das komplexere, kann verworfen werden. Wir stellen außerdem fest: Beide Modelle weisen einen signifikanten Erklärungsgehalt auf, sie sind besser als das Nullmodell.

## **5. Comparison of the Models / Model's Performance on Test Data**

### **5.1 Quantitative**

#### **5.1.1 Confusion Matrix**

#### **5.1.2 Accuracy**

#### **5.1.2 Precision, Recall and F1-Score**

### **5.2 Qualitative**

### **5.3 Overfitting Check**

## **6. Visual Representation**

## **7. Final Discussion**
